

## Two sum

Given an array of integers `nums` and an integer `target`, return indices of 2 numbers such that they add up to `target`. You may assume that each input would have exactly one solution, and you may not use the same element twice. You can return the answer in any order.

Ex:

Input: `nums = [3, 2, 4]`, `target = 6`

Output: `[1, 2]`

constraints

- $2 \leq \text{nums.length} \leq 10^4$
- $-10^9 \leq \text{nums}[i] \leq 10^9$
- $-10^9 \leq \text{target} \leq 10^9$

## Logic:

- initialize a variable `sum` to 0
- get the length of array and store it in a variable `n`
- use two for loops to check every possible pair of numbers in the array
  - ↳ The outer loop iterates through first element (index `i=0` to `i=n-1`)
  - ↳ The inner loop iterates through second element (index `j=i+1` to `n-1`).
- for each pair of elements calculate sum:  $\text{sum} = \text{nums}[i] + \text{nums}[j]$
- check if `sum` is equal to `target`
- if `sum == target`, **Break** the loop & return the indices
- if no pair sum matches `target`, return empty array.

```
class solution {
```

```
public int[] twosum(int[] nums, int target)
```

```
    int sum=0;
```

```
    int n = nums.length;
```

```
    for (int i=0; i<n; i++) {
```

```
        for (int j=i+1; j<n; j++) {
```

```
            sum = nums[i] + nums[j];
```

```
            if (sum == target) {
```

```
                return new int[] { i, j };
```

```
            }
```

```
        }
```

```
    return new int[] { };
```

```
}
```
